# Information Theoretic Approaches for Predictive Models Results and Analysis

Monica Dinculescu Supervised by Doina Precup

### Undergraduate Summer Research Symposium August 31, 2006

# **Problem** Definition

- Partially observable system, discrete time
- Hidden states: you can't see a state, but you can see an observation

[Littman, Sutton and Singh, 2001]

4 3 b

Partially Observable Markov Decision Processes Predictive State Representations

# Problem Definition (cont'd)

#### Definitions

$$x_t^{past} \in X$$
 : histories (pasts)

• finite length sequences of action:observation pairs  $x_t^{past} = [a_{t-k} : o_{t-k}, ..., a_{t-1} : o_{t-1}]$ 

 $y_t^{fut} \in Y$ : future observations

• Want to be able to predict what the outcome of an action will be: i.e. predict  $p(y_t^{fut}|a_t, x_t^{past})$

Partially Observable Markov Decision Processes Predictive State Representations

### Solution | Partially Observable Markov Decision Processes

## • POMDP [Sondik, 1971]

#### Definition

A **belief state** is used to keep track of the probabilities of being in each of the hidden states. [Sondik, 1971]

#### Problem

- Computationally expensive
- Depends on a good model of underlying states

イロト イ得ト イヨト イヨト

Partially Observable Markov Decision Processes Predictive State Representations

### Solution || Predictive State Representations

- PSR [Littman, Sutton and Singh, 2001]
- Constructs a state representation based only on actions and observations

### Definitions

A test is a sequence of future action:observation pairs

• 
$$q = [a_t : o_t, ..., a_{t+1} : o_{t+1}]$$

A history is a sequence of past action:observation pairs

• 
$$h = x_t^{past} = [a_{t-k} : o_{t-k}, ..., a_{t-1} : o_{t-1}]$$

• PSR representation predicts p(q|h)

Partially Observable Markov Decision Processes Predictive State Representations

## Solution II (cont'd) Predictive State Representations

### Definition

- A System Dynamics Matrix is an ordering over all possible tests and histories.[Singh, James et al, 2004]
- Infinite matrix but with a finite number of linearly independent columns called **core tests**.

$$\begin{array}{c|c} \mathbf{h}_{1} = \phi & \mathbf{t}_{1} & \cdots & \mathbf{t}_{j} & \cdots \\ \mathbf{h}_{1} = \phi & \mathbf{p}(\mathbf{t}_{1} \mid \mathbf{h}_{1}) & \mathbf{p}(\mathbf{t}_{j} \mid \mathbf{h}_{1}) \\ \mathbf{h}_{2} & \vdots \\ \vdots & & \\ \mathbf{h}_{i} & \mathbf{p}(\mathbf{t}_{1} \mid \mathbf{h}_{i}) & \mathbf{p}(\mathbf{t}_{j} \mid \mathbf{h}_{i}) \\ \vdots & & \\ \end{array}$$

A (1) > A (2) > A

-

[Singh, James et al, 2004]

#### Problem

- Less restrictive model but very data expensive
- No good learning algorithms

Monica Dinculescu Information Theoretic Approaches for Predictive Models

# Motivation

- Flexible model based on finite length histories
- Data efficient learning algorithm
- Computation/memory affordable
- Good predictions

• = • •

# Information Theoretical Approach

 Based on the Active Learning algorithm developed by S.Still and W.Bialek, 2004

### Definition

We define an internal representation  $s_t \in S$  such that:

- **1** There is a lossy compression of the information from  $x_t^{past}$
- It has a good predictive power

Optimization Principle Algorithm Results

# **Optimization** Principle

#### Definition

$$F = max_{p(s_t|x_t^{past})}[I(\{s_t, a_t\}, y_t^{fut}) - \lambda I(s_t, x_t^{past})]$$

- First term: maximize predictive information about the future
- Second term: compress information about the past
- $\lambda$  is a constant that trades 1) and 2) off

4 3 5 4

Introduction	Optimization	Principle
T Approach	Algorithm	
Conclusion	Results	

# Solution

#### Theorem

 $\begin{array}{l} The \ s_t \leftarrow x_t^{past} \ assignment \ is: \\ p(s_t | x_t^{past}) \sim exp(\frac{-1}{\lambda} \sum_a p(a_t | x_t^{past}) \cdot D_{KL}[p(y_t^{fut} | a_t, x_t^{past}) || p(y_t^{fut} | a_t, s_t)] \end{array}$ 

- The *D<sub>KL</sub>* compares how different the future prediction as given by the state is compared to the future prediction as given by the entire history
- A better state assignment →a prediction more similar to the one returned by the history
- $\lambda$  acts as a temperature parameter; as  $\lambda \to 0$ , the  $s_t \leftarrow x_t^{past}$ assignment becomes deterministic

# Algorithm

**Input:** # states  $s_t$ , length of  $x_t^{past}$ , length of initial trajectory,  $\lambda$ **Output:**  $\rho(s_t | x_t^{past})$ 

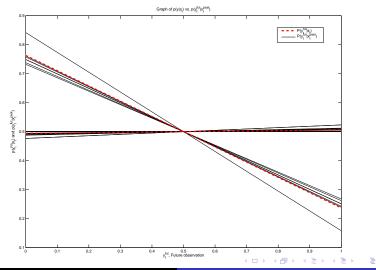

- Create an initial trajectory by taking random actions
- 2 estimate  $p(x_t^{past})$  and  $p(y_t^{fut}|x_t^{past}, a_t)$
- **③** for i←1 to t
- while  $p(s_t|x_t^{past})$  does not converge

$$\begin{array}{l} \hline \textbf{S} & \text{iteratively solve:} \\ p^{(j+1)}(y_t^{fut}|a_t,s_t) \sim & \frac{\sum_h p(y_t^{fut}|a_t,x_t^{past})p(a_t|x_t^{past})p^{(j)}(s_t|x_t^{past})p(x_t^{past})}{\sum_h p(a_t|x_t^{past})p^{(j)}(s_t|x_t^{past})p(x_t^{past})} \\ p^{(j)}(s_t|x_t^{past}) \sim exp(\frac{-1}{\lambda}\sum_a p(a_t|x_t^{past}) \cdot D_{KL}[p(y_t^{fut}|a_t,x_t^{past})||p^{(j)}(y_t^{fut}|a_t,s_t)] \\ \hline \textbf{S} & \text{take a random action } a_t \text{ and update } p(x_t^{past}) \text{ and} \\ p(y_t^{fut}|x_t^{past},a_t) \end{array}$$

# Conclusions and Future Work

- The algorithm learns a predictive model with a limited amount of data
- Predictions are consistent
- Future Work:
  - Compare predictive model with PSRs
  - Learn optimal action policies
